## HIGHLIGHTS OF TV VIOLENCE PROFILE NO. 8

(March 1977)

Television violence increased sharply in all categories including "family viewing" and children's program time on all three networks.

The increase resulted in the highest Violence Index on record. The only score that comes close to the current record of 203.6 was the score of 198.7 in 1967, the year of turmoil that led to the establishment of the Eisenhower Violence Commission and our TV Violence Index.

Other components of the TV Violence Profile confirmed previous findings of the unequal structure of power and risk in the world of television drama, and showed children's particular vulnerability to the effects of television. Heavy viewers revealed a significantly higher sense of personal risk, of law-enforcement, and of mistrust and suspicion than did light viewers in the same demographic groups, exposed to the same real risks of life. The results also showed that TV's independent contributions to the cultivation of these conceptions of a "mean world" and other aspects of social reality are not significantly altered by sex, age, education, income, newspaper reading, and church attendance.

The Violence Profile is a cluster of indices sensitive to different aspects of the nature and effects as well as the amount of violence on television. The Violence Index itself is a composite of measures of the prevalence, rate, and characterizations involved in violent action.

The latest Violence Index was based on the analysis of a fall 1976 sample of prime time, late evening, and weekend daytime network television dramatic

programming. The analysis focused on clear-cut and unambiguous physical expressions of overt violence in any context. (Available evidence suggests that violence in a humorous or fantasy context may be at least as effective a demonstration of some of its social lessons as "realistic" or "serious" violence.)

Figure 1 shows that the percentage of characters involved in violence and killing (CS) rose to the second highest, and the indicator of violent action in programs (PS) to the highest point on record. Three-fourths (74.9 percent) of all characters were involved in some violence compared to 65 percent in 1975. Nine out of every ten programs sampled (89.1 percent) contained some violence, compared to 78.4 percent in 1975. The saturation of programs with violence, indicated by the rate of violent episodes, rose to record heights of 6.2 per play and 9.5 per hour, compared to 5.6 and 8.1, respectively. Only killing declined slightly. The cumulative effect of the increases resulted in the unprecedented jump in the composite Violence Index. (The detailed figures and the precise composition of the Violence Index can be seen on Table 1 of the full report.)

The increase in violence cuts across program categories and times. The context of dramatic programming did not change significantly, eliminating the possibility that the upsurge of violence was due to a sudden jump in the number of action programs, or late evening, cartoon, new, or "serious" programs in the sample. (These figures can be seen in Tables A through F of the full report.)

All three networks increased their overall mix of violence but stayed in the same violence rank order as in 1975 with NBC the highest, ABC second, and CBS third. A network-by-network comparison shows the following rounded

Violence Index scores for 1975 and 1976:

	ABC		CBS		NBC	
	1975	1976	1975	1976	1975	1976
Overall index	187	207	155	181	201	224
"Family viewing" time (8-9 p.m. EST)	121	197	60	101	126	139
Late evening (9-11 p.m. EST)	232	196	176	175	224	282
Weekend (children's) hours (Sat. & Sun. daytime)	201	237	218	239	252	264

The 10-year trends are shown in Figures 2 through 7. Figure 2 gives the Violence Index for different hours of programming for all networks. Figure 3 presents the Violence Index for different hours of programming by each network. Figures 4 through 7 provide direct network comparisons separately for the overall Index, "family viewing time," late evening, and weekend (children's) programs.

As in 1975, NBC is the "leader" in overall violence and in both children's hours and late evening violence. ABC is in the middle in overall violence, due to a decline in late evening violence (in which it had been the highest before), and despite increases in "family viewing" and children's hours. CBS, leader in the "family viewing" concept, lifted its two-season lid on "family viewing time" violence, but still held the lowest "family viewing time," late evening, and overall violence scores. Children's hour violence on CBS rose to above that of ABC, but below that of NBC.

The Violence Index ranks CBS least and NBC most violent overall, CBS least and ABC most violent in "family viewing time," CBS least and NBC most violent in late evening, and ABC least and NBC most violent in weekend children's program time. (Detailed figures can be found in Tables 1 through 43 of the full report.)

daytime (children's) programs only

Other components of the Violence Profile deal with the structure of power demonstrated in TV violence and with conceptions of social reality that television viewing cultivates in the minds of viewers.

The most elementary -- and telling -- social structure involved in a violence scenario is that of violents and victims. The ratios of those who inflict and those who suffer violence provide a calculus of life's chances for different groups of people in the world of television drama. These Risk Ratios are obtained by dividing the more numerous of these two roles by the less numerous within each group. A plus sign indicates that there are more violents or killers than victims or killed and a minus sign indicates that there are more victims or killed than violents or killers.

The overall Violence-Victim Ratio since 1969 (when this measure was developed) is -1.21, meaning that for every violent there were 1.21 victims. However, while the overall victimization ratio for men is -1.20, for women it is higher: -1.32. Even more striking are the differential risks of fatal victimization. There were nearly two male killers for every male killed (Killer-Killed Ratio of +1.96). However, for every female killer, one woman was killed (K-K Ratio of 1.00).

Particularly high risks of victimization (relative to the ability to inflict violence) are borne by children (-1.73), old women (-3.00), unmarried women (-1.50), lower class women (-2.25), nonwhites (-1.40) and particularly nonwhite women (-2.50). "Good" characters were more likely to be victimized (-1.28) than "bad" characters (-1.02), although the latter were more often fatal victims. "Good" women were even more likely victims (-1.47) than "good" men (-1.24). But "bad" women had the most favorable (and only positive) Violent-Victim Ratio of all groups (+1.16). Committing

violence seems more likely to mark a female than a male character "bad" in the world of television.

Exceptionally high relative risks of fatal victimization are borne by the old and the poor, particularly among women. (Detailed findings can be found in Tables 44 through 64, with a summary in Table 65 of the full report.)

Although the pattern of relative victimization has been fairly stable from year to year, the overall Violent-Victim Ratio declined from -1.25 in 1975 to -1.06 in 1976, suggesting a possible decrease in overall victimization. However, the relative power positions of different sex, age, and social groups did not change.

The patterns of viewer responses to questions about social reality given by different groups of children and adults confirm previous findings that the cultivation of fear and mistrust may be among the most pervasive effects of heavy exposure to the violent and risky world of television drama. In giving the "television answer" to questions about violence, law enforcement, and trust, children tended to score higher and learn more from television than adults. Heavy viewers in all sex, age, education, income, reading, and church attendance groups were more imbued with the television view of a "mean world" than were light viewers in the same groups. (Detailed results can be seen in Tables 68-71 of the full report.)

## VIOLENCE PROFILE NO. 8; 1967-1976

Americans live much of their lives in the world of television drama. Children and adults alike are exposed to vivid patterns of the facts of life in that world. What are those facts, especially with regard to the context, structure, and functions of violence, and what lessons do children and adults derive from their exposure to those facts?

These are the basic questions addressed in the research that yields the Violence Profile. Trends in network television drama and the conceptions of social reality that viewing tends to cultivate in the minds of viewers are studied in a continuing project called Cultural Indicators (funded by NIMH). The research is designed to provide annual indicators of network television's dramatic content and its effects on child and adult viewers.

The Violence Profile is a set of multidimensional indicators of trends in violence in television drama and their correlates in viewers' conceptions of social reality. The continuing research from which this report is drawn has investigated the extent, nature, and symbolic functions of violence in network television drama since 1967, and the conceptions of social reality television viewing cultivates since 1973.

The research began with the investigation of violence in network television drama in 1967-68 for the National Commission on the Causes and Prevention of Violence. It continued through 1972 under the sponsorship of the Surgeon General's Scientific Advisory Committee on Television and Social Behavior, and since then under grants from the National Institute of Mental Health. The study was broadly conceived from the beginning to show the role and symbolic

functions, as well as the extent, of violence in the world of television drama. A conference of research consultants to the National Institute of Mental Health in the spring of 1972 recommended that the Violence Index be further broadened to take into account social relationships and viewer conceptions. Implementing that recommendation, we developed the Violence Profile including violence-victim ratios and viewer responses.

The Violence Profile consists of indicators of (1) the program context in which dramatic violence occurs, (2) the prevalence, rate, and roles of violence that make up the Violence Index, (3) the structure of power in the world of television drama as indicated by the different risks of violence and victimization for different groups in the fictional population, and (4) the extent to which (and ways in which) television cultivates its own view of facts and aspects of social reality in the conceptions of its audiences.

The first three measures of the Violence Profile reflect trends in the content of network television drama. They come from our comprehensive and periodic study of that content called Message System Analysis. The fourth, or "effects" indicators come from our study of viewer conception cultivated by that content, called Cultivation Analysis. The detailed tabulations presenting the relevant findings of Message System Analysis and of Cultivation Analysis appear at the end of this report, following a description of the analytical procedures themselves.

#### MESSAGE SYSTEM ANALYSIS

Large and representative aggregates of television output (rather than individual selections from it) are the system of messages to which total communities (rather than selective individuals or groups) are exposed. Message

system analysis does not deal with single works, subjective perceptions, or dramatic subtleties. It focuses on the gross, unambiguous, and commonly understood facts of portrayal. These are the features that can be expected to provide bases for interaction and common assumptions and definitions (though not necessarily agreement) among large and heterogeneous mass publics.

Message system analysis has been performed on annual sample-weeks of prime time and Saturday daytime network dramatic programming since 1967 by trained analysts who observed and coded various aspects of TV content by the most reliable methods employed in any research of this kind.

The purpose of the analysis is to provide systematic, cumulative, and objective observations representing relevant aspects of the world of television drama. The analysis yielded the basic data for the construction of indicators of trends in the dramatic context, in the prevalence, rate, and dramatic roles involved in violence, and in power relationships expressed by the distribution of risks to different groups in the fictional population. These indicators will be described after a discussion of definitions, units, samples, data collection procedures, and reliability tests of the message system analysis.

#### Definition of violence

Our definition of violence is "the overt expression of physical force against self or other, or compelling action against one's will on pain of being hurt or killed, or actually hurting or killing." The action may be "accidental," it may be "humorous" or "serious," but idle threats or purely verbal gestures are not included,

There are, of course, no unintended "accidents" in fiction and drama. "Accidents" and "acts of nature" have the effect, if not purpose, of characterizing or justifying the victimization and fate of certain types of characters. Therefore, they may cultivate important lessons about social

typing, relative vulnerability, a sense of risk in life, etc. Similarly (as available evidence tends to indicate), violence in a humorous or fantasy context may be at times an even more effective demonstration of at least some of the implicit lessons of violence than "realistic" or "serious" violence. At any rate, TV viewers watch all types and are exposed, therefore, to overall patterns that cut across styles of presentation. These common patterns are the primary goals of this investigation.

The analysis thus focuses on clear-cut, obvious, and unambiguous physical expression of violence in any context, without a priori assumptions about what types of manifest violence might have what kinds of effects. The investigation of effects is the task of Cultivation Analysis, discussed later in this report.

#### Units of Analysis

Observations are recorded in three types of units: the program as a whole, each specific violent action (if any) in the program, and each dramatic character appearing in the program.

"Program" means a single fictional story presented in dramatic form. This may be a play produced for television, a feature film telecast during the period of the study, or a cartoon story (of which there may be one or more in a single program). Each of these would be analyzed separately and recorded as a "program"; thus the basic unit is actually the play. All such programs telecast during the study periods were analyzed whether or not they contained violence.

Violent action means a scene of some violence confined to the same parties. If a scene is interrupted (by flashback, or shift to another scene) but continues in "real time," it is still the same act. However, if a new agent of violence enters the scene, that begins another act. These units are also called violent episodes.

Characters analyzed in all programs (whether violent or not) are of two types. Major characters are the principal roles essential to the story. Minor characters (subjected to a less detailed analysis) are all other speaking roles. (The findings summarized in this report include the analysis of major characters only.)

#### Samples of programming

Because nationally distributed programs provide the most broadly shared TV dramatic fare, network dramatic programs transmitted in evening prime time (8 p.m. to 11 p.m. each day), and network children's dramatic programs transmitted weekend mornings (Saturday and Sunday between 8 a.m. and 2 p.m.) comprise the analytical source material.\*

The annual sample consists of videotaped programs broadcast in one week during the fall TV "season." When and if an episode of a regularly scheduled program is pre-empted by some special offering during the selected week, the next available episode of that series is videotaped. This replacement procedure is also used for those rare occasions when video-recorder failure results in the loss of a program during the scheduled sample week.

---

\*In 1967 and 1968, the hours included were 7:30 to 10 p.m. Monday through Saturday, 7 to 10 p.m. Sunday, and children's program 8 a.m. to noon Saturday. Beginning in 1969, these hours were expanded until 11 p.m. each evening and from 7 a.m. to 2:30 p.m. Saturday and Sunday. As of 1971 however, network evening programming has been reduced by the FCC's prime time access rule. The effective evening parameters since 1971 are therefore 8 to 11 p.m. Monday through Saturday and 7:00 to 11:00 p.m. Sunday.

Although the sheer numbers involved make empirical estimation of sampling error for all of the dimensions in the recording instrument prohibitive, with respect to four basic sample dimensions -- network, program format (TV play, cartoon, feature film), type (action, comedy, etc.), and tone (humorous, serious) -- the solid week sample is at least as generalizable to a year's programming as larger randomly drawn samples. In a sampling experiment executed in connection with the 1967-68 study, a sample of 365 programs was constructed according to the parameters of the 1967-68 project's sample, except that it was drawn according to a one-program-per-day random selection procedure, for a calendar year that approximately bridged the interval between the 1967 and 1968 one-week samples.\* There was no significant difference in the distribution of programs by network, format, type and tone (as defined for the 1967-68 project) between the experimental and solid-week samples.

Two further sampling experiments were conducted in the spring of 1975 and 1976. A week's sample from each spring's programming was analyzed and compared with the fall samples for differences in the violence indices. (The results of the two spring season analyses are separately reported in all tabulations in columns marked with an S before the year. Thus S1975 and S1976 stand for spring 1975 and 1976 seasons, 1975 and 1976 for fall seasons.) Few differences were found and they did not seem to warrant continuing the spring sampling. Another test of our sample, using a 7-week period as its base, is now underway.

#### Coding and training procedures

For the analysis of each program sample, a staff of between 18-24 coders

---

\*Eleey, Michael F., "Variations in Generalizability Resulting from Sampling Characteristics of Content Analysis Data: A Case Study." The Annenberg School of Communications, University of Pennsylvania, 1969.

is recruited. The initial period requires about three weeks of instruction and testing. Several introductory sessions are devoted to item-by-item discussion of the recording instrument. The trainee group is subsequently split into randomly assigned coding teams of two each, and all pairs then view and code three selected programs. Each coding pair works independently of all other pairs, and returns one joint coding for each program. In the next general meeting, the entire staff discusses the difficulties encountered in the three-program exercise. When these problems have been resolved, the coder-pairs return to code seven additional programs selected from the tape archive for this training purpose.

The data generated by the coder-pairs on the ten training programs is keypunched and subjected to computerized agreement analysis. On the basis of these results, instructions are further discussed and perhaps revised, and idiosyncratic coder pairs are assigned to other tasks or dismissed. Coder pairs who survive this testing process proceed to analyze the season's videotaped program sample.

During both the training and data-collection phases, coder pairs monitor their assigned videotaped programs as often as necessary, re-screening portions as needed. All programs in the sample are recorded independently by two separate coder-pairs to provide double-coded data for reliability comparisons. (For budgetary reasons, only 30% of the programs in the 1967-1968 analysis were coded a second time.)

A final data set for subsequent analysis is compiled from the full data base by randomly selecting one of the two codings for each program. As a last check against deviant coding, reliability measures are computed for each

pair, before the final selection. This procedure would identify problem coders who may not have been screened out in the training and pretest phase. In such an instance, the data recorded by the questionable pair would be excluded from the selection, and the alternative coding used. (Over the course of this study, only one such case has been encountered.)

#### Assessment of reliability

The purpose of reliability measures in content analysis is to ascertain the degree to which the recorded data are consistently representative of the material being studied and do not reflect observer bias or instrument ambiguity. Theoretically both types of contamination can be corrected by refining the instrument and/or by intensifying coder training, or, as a last resort, by eliminating the unsalvageable variable or dismissing the incorrigible coders. Thus measures of reliability may serve two functions: (1) as diagnostic tools in the confirmation of the recording instrument, and (2) as arbiters of the replicability of the procedure, assuring confidence in the final data. In this project, they serve both: during the preliminary period of instrument revision and coder training, they provide direction to the problem areas in the recording process; the final measures computed on the study's entire corpus of double-coded data determine the acceptability of information for analysis, and provide guidelines for its interpretation.

Agreement due merely to chance gives no indication that the data truly reflect the phenomena under observation. Simple percent-agreement measures are therefore inadequate indicators of reliability, since they fail to account for the amount of agreement expected by chance. Reliability measures

in the form of agreement coefficients, however, indicate the degree to which agreement among independent observers is above chance. In general, then,

$$\text{Coefficient of agreement} = 1 - \frac{\text{observed disagreement}}{\text{expected disagreement}}$$

Values for coefficients of this form will range from plus one when agreement is perfect, to zero when agreement is purely accidental (or perfectly random), to negative values when agreement is less than that expected due to chance. These coefficients will generally give more conservative estimates of reliability than will simple percent-agreement measures.

Five computational formulas are available for calculating the agreement coefficient. The variations are distinguished by different formulations of the disagreement function -- depending on whether the variable is considered to constitute a nominal, ordinal, interval, bipolar or ratio scale. Except for their respective scale-appropriate sensitivity to deviations from perfect agreement, all formulas make the same basic assumptions as the prototype for nominal scales devised by Scott.\* Thus in the case of the binary variable, all five formulas yield identical results.\*\*

---

\*Scott, William A. "Reliability of Content Analysis: The Case of Nominal Scale Coding," *Public Opinion Quarterly*, 17:3:321-325, 1955.

\*\*For a formal discussion of part of this family of coefficients, see Klaus Krippendorff, "Bivariate Agreement Coefficients for the Reliability of Data." In E. F. Borgatta and G. W. Bohrnstedt (eds.), *Sociological Methodology*, 1970, (San Francisco: Jossey-Bass, Inc.)

The project's double-coded sample of data is analyzed for agreement via these coefficients, with the aid of a recently developed computer program.\* The cumulative reliability results for both the items and the compound measures and indicators govern the reporting of the results.

#### VIOLENCE INDEX AND RATIOS

Message system analysis contributes three types of information to the Violence Profile. The first is the program context of which any dramatic element, such as violence, is an integral part. The second consists of the specific indicators of violence in various program categories, and the composite Violence Index. The third type of information is in the form of risk ratios and scores which show how the pattern of violence and victimization works out for different kinds of people in the world of television drama.

##### Program context

Trends in programming and in such characteristics of the plays as their comic or serious tone provide the background against which specific manifestations of violence may be seen. The proportions of feature films, cartoons, television programs, and especially of "action drama" in the overall programming also have a major effect on the incidence of violence. Tables A through F present these contextual features of programming.

### Indicators of violence

Three sets of measures have been computed from the direct observational data of the message system analysis. They show the extent to which violence occurred at all in the program samples, the frequency and rate of violent episodes, and the number of roles calling for characterizations as violents, victims, or both. These are called prevalence, rate, and role, respectively.

Prevalence. The percent of programs containing any violence indicates the prevalence (as compared to frequency or rate) of violence in a particular program sample. Prevalence is calculated both as percent of programs (%P) and as percent of program hours containing violence, but only %P is included in the Index.

Rate. As measures of prevalence indicate the proportion of program units in which one or more acts of violence occur, so rate expresses the frequency of these acts in units of programming and in units of time. The acts themselves are called "violent episodes," defined as scenes of some violence confined to the same characters. The number of such episodes divided by the total number of plays (violent or not) yields the rate of program (R/P). The rate per hour (R/H) is the number of episodes divided by the number of program hours in the sample. The latter measures the concentration or saturation of violence in time, and compensates for the difference in rates between a long program unit (such as a feature film) and a short one (such as a 15-minute cartoon).

Roles. The portrayal of characters as violents (committing violence) or victims (subjected to violence), or both, yields several measures. They are: percent of violents out of all characters in a sample; percent of

victims out of all characters in a sample; all those involved as violents or as victims or both (%V); percent of killers (those committing fatal violence); percent killed (victims of lethal violence); and all those involved in killing either as killers or as killed (%K).

#### Composite scores and the Violence Index

The above measures of violence are based on analysts' observations. They are provided in all tabulations and should be used as the basic indicators of trends. However, for ease of illustration and comparison, they are combined to form summary scores and an index. These are not statistical findings in themselves, and should not be treated as such. Rather they serve as convenient illustrators of the basic findings and to facilitate gross comparisons.

The two scores are based on selected measures showing qualities of programs and of characterizations, respectively. Prevalence (%P), rate per program (R/P), and rate per hour (R/H) are reflected in the program score (PS). This is computed as follows:

$$PS = (%P) + 2(R/P) + 2(R/H)$$

In the formula, %P is the percent of programs containing violence, R/P is the rate of violent episodes per play, and R/H is the rate per hour. The rates R/P and R/H are doubled in order to raise their relatively low numerical value to the importance that the concepts of the frequency and saturation of violence deserve. Nevertheless, the program score gives the greatest weight to the extent to which violence prevails at all in the programs. Secondary weight is given to the frequency of violence and the saturation of the programs with violent action.

Roles involving characters in any violence, weighted by roles involved in killing, are expressed in the character score (CS). The formula

$$CS = (%V) + (%K)$$

represents the percent of all leading characters committing violence, suffering violence, or both (%V), with added weight given to the percent of those involved in killing either as killers or as victims, or both (%K).

Finally, the Violence Index is obtained by adding the program score to the character score. Prevalence, rate, and role are thus reflected in the Index, with program information usually weighing slightly more heavily in the balance than information derived from character analysis. All these measures and indicators are tabulated for all years by different program samples in Tables 1 through 43.

#### Indicators of power: Risk Ratios

The most elementary -- and telling -- relationship involved in violent action is that of violent and victim. The pattern of those who inflict and those who suffer injury or death provides a differential calculus of life's chances for different groups of people in the world of television drama. That pattern is expressed in the trends and comparisons of Risk Ratios (victims divided by violents or violents by victims within the same groups) and Character V Scores (percents of characters involved in any violence plus percents involved in killing) given in Tables 44 through 64. A summary of Risk Ratios for all years for male and female characters by age, marital status, class, nationality, race, and type ("good" vs. "bad," etc.) appears as Table 65. A minus ratio indicates more victims, a plus ratio more perpetrators of violence.

#### CULTIVATION ANALYSIS

Cultivation analysis begins with the patterns found in the "world" of television drama. The common message systems composing that world present

a coherent image of life and society. How is this image reflected in the images, expectations, definitions, interpretations and values held by its audiences? How are the "lessons" of symbolic behavior derived from other times and places, and presented in synthetic, fictional contexts, applied to assumptions about real life?

Clearly, the impact of the television world on the real world of the viewers is subtle and complex, and its investigation requires sustained and comprehensive effort. In order to develop procedures for the investigation of the cultivation effects of the message systems to which large viewing publics (and, indirectly, the entire community) are exposed, it is necessary to utilize an extensive data base and to develop new tools and techniques.

#### Interface with Message System Analysis

Our strategy for the investigation of television effects upon specific facts and conceptions of social reality begins with the analysis of the world of television drama. We derive from Message System Analysis those "facts" and aspects of social reality which television drama presents in a characteristically particular or peculiar fashion, at least in comparison with other conceptions of those facts and aspects (such as Census figures) derived from direct and independent observation. For example, ten years of television drama showed 64.4 percent of all characters encountering some violence either as perpetrators or as victims or both (Table 1). According to the 1970 Census, there were only .32 violent crimes per 100 persons.\* In the world of television, therefore, one has a 64 percent chance of encountering violence; in the real world, one-third of 1 percent. Does TV viewing affect people's conceptions of these chances?

The next step is to ascertain what samples of heavy and light viewers (both children and adults) believe these facts of life really are. To the

\*Newer data on personal violent crime victimization range from .41 per 100 persons (based on 1973 Police reported figures which include homicide) to 3.3 per 100 persons over 12 (based on 1974 national probability sample data which doesn't include homicide).

extent that patterns of life presented in dramatic television cultivate real-life conceptions of social reality, heavy viewers should be more likely than light viewers to choose the answers that reflect the television view of life. Our research strategy, instrumentation and samples are designed to establish the extent to which and the ways in which television does cultivate such patterns of responses.

#### Strategy, instrumentation, and samples

Having developed the "television view" and the "real world" (or simply another) view of selected facts and aspects of social reality, we constructed questionnaires dealing with those facts and aspects of life. Each question has a "television answer" reflecting the "television view" of the facts and another or "non-television answer." For example one such question asks: "During any given week, what are your chances of being involved in some kind of violence? About one in Ten? About one in a hundred?" "About one in ten" is closer to the television view and is used as the "television answer." (The real TV answer would be just as implausible as the Census answer.) This is a forced error choice type item, similar to those used by Hammond,\* which requires the respondent to select one of two or more answers to a factual question. All the answers may be incorrect (as in the examples above), but they are chosen to reflect either the bias that is characteristic of television or to represent a bias in a direction opposite to that which would be found on television. Will heavy viewers more than light viewers choose answers that reflect a "television" rather than a "non-television" (which often means "real world") bias? The answer is yes and can be found on Tables 69-70.

---

\*Hammond, K. R., "Measuring Attitudes by Error Choice: An Indirect Method," Journal of Abnormal and Social Psychology, 43:38-48, 1948.

Another type of item is designed to test some opinion and attitude questions to which television presents peculiar answers. For example, violent television suggests that most people cannot be trusted. Is that also more the view of heavy than light viewers? The answer is yes, and can be found on Tables 69-70.

Our questionnaires have been developed and adapted for a variety of respondent groups of adults and children. In cases where we found that other researchers have asked questions which relate to our design and have also gathered information on the television viewing habits of their respondents, we have performed secondary analyses on their data.

Nine Cultivation Analysis data bases have yielded the results reported here. Five are samples of adults and four are children's samples. The adult samples (described in Table 66) are those commissioned for or obtained by this study from the survey research organization of Starch-Hooper, the Opinion Research Corporation, and the National Opinion Research Center, and one survey conducted by our staff and students at the University of Pennsylvania. The children's samples (described in Table 67) consist of repeated administrations of our questionnaires to students in a New Jersey public middle-school and of the Bank Street School in New York City. Tables 66 and 67 present the details of these samples and of methods of data collection.

#### Cultivation Indicators

Indicators of conceptions of social reality that television cultivates in the minds of viewers compose the fourth and final component of the Violence Profile. They highlight the effects of heavy television viewing for different groups and in relation to various socio-economic, educational, cultural, and (other) media consumption characteristics and activities.

To summarize larger patterns of responses, we have combined the answers to sets of related questions. Table 68 lists one group of questions combined into a Cultivation Index relating to some assumptions about the facts of violence and law enforcement. The Table shows the relationship between each component question, its source in the message analysis data, and the corresponding "real world" figure.

Such an Index can be used to compute relationships between the answers given by our respondents and their levels of television viewing, controlling for a variety of important demographic and individual characteristics. In Table 69 we show the zero-order and partial correlations of the violence and law enforcement Cultivation Index with amount of television viewing for two adult and two children's samples.

The analysis shows a significant tendency for heavy viewers to overestimate the prevalence of violence, compared to that exhibited by light viewers. The analysis also demonstrates that the television Cultivation effects cannot be accounted for in terms of the major demographic variables of age, sex, education or even, in the case of our New Jersey Children's sample, I.Q. Controlling for these variables, we still find a positive and significant relationship between our Cultivation Index and amounts of television viewing. In each sample, television viewing is significantly associated with giving "television answers" to our questions, and the partial correlations show that the relationships remain positive and, in 19 out of 22 cases, significant when controls are added, singly or together. The effects are consistent and robust across a range of undoubtedly powerful control comparisons.

In one of our secondary analyses we looked at three questions used on the NORC 1975 General Social Survey which seem to reflect a generalized sense

of mistrust and suspicion. Looking at the responses of adult and (having added these questions to the survey we conducted among children at the Bank Street School) child heavy and light viewers of television, we find that television indeed cultivates such attitudes. The heavy viewers, both child and adult, were consistently more likely to choose an answer which reflected a sense of mistrust and suspicion. Table 70 shows the overall pattern of answers by two samples of viewers to this group of what we have called "mean world" questions. The differences between the answers given by the light, medium and heavy viewers (in the case of Bank Street, viewing levels did not permit us to identify heavy viewers in our usual terms) are shown as "Cultivation Differentials" indicating the patterns of association between television viewing and giving "television answers" to our questions.

We have combined these questions into a "Mean World Index" shown on Table 71. Cultivation differentials (and statistical tests of association strength) are presented and a variety of controls are applied. In the adult sample we see that the greater likelihood of giving television answers among heavy viewers retains (or increases) its strength with sex, age, education, income, newspaper reading and church attendance

Blacks, as a whole, do not show this association; although those blacks in the sample who are college educated or whose income is over \$8,000 do show the same cultivation pattern found among white respondents. In general, the level of mistrust evidenced by black heavy and light viewers is higher than that for whites, although the relatively small number of blacks in a representative, proportional national sample precludes a definitive analysis at this stage.

In the children's sample, the patterns of significant association are maintained with sex, age, parent's socioeconomic status, and newspaper reading controlled.

The patterns again show evidence of the existence of a "television generation," and of the greater cultivating power of television among children than among adults. In general, heavy viewers growing up with television (under 30) tend to be more imbued with the television view of life than those growing up before television (over 30), and children exhibit generally higher Cultivation Differentials than do adults.

#### TABLES

The detailed findings comprising Violence Profile No. 8 are given in the tabulations that follow. The four sets of measures from which indicators of trends in television violence and its symbolic functions can be constructed deal with (1) program context, (2) violence measures and indices, (3) Risk Ratios, and (4) Cultivation Indicators.

Tables A though F present the context of trends in the format, type, and tone dimensions of programming.

Annual monitoring sample dimensions, indicators of Prevalence, Rate, and Role, and Composite Scores and Indices are given in Tables 1 through 43. The first 22 Tables present all measures and Indices by time of telecast, format, and type of program. Tables 23 through 43 give selected information separately by network.

Tables 44 through 65 give detailed trend information on Risk Ratios by time and type of programs, and sex, age, marital status, class, nationality, race, and type ("good" vs. "bad," etc.) of characters. The violent-victim and killer-killed Risk Ratios are obtained by dividing the larger by the smaller classification within each group. The minus Ratio indicates more victims, a plus Ratio more perpetrators of violence. Minus 0.00 means only victims, plus 0.00 only violents.

For reasons of space, results for 1967 and 1968 and results for 1969, 1970, and 1971 are combined. (Separate annual data are in Violence Profile No. 7.) All monitoring was based on fall season samples except additional spring samples in 1975 and 1976, presented in the S1975 and S1976 columns.

Tables 66 through 71 present the samples and results of the Cultivation Analysis.

Note: Character score is the percent of characters involved in any violence plus the percent involved in any killing. V-V ratio is of violents (+) and victims (-). K-K ratio is of killers (-) and killed (\*). If 0.00 is preceded by a sign, group has either no violents or no victims; +0.00 means only violent(s), -0.00 means only victim(s).

TABLE 68: DATA SOURCES FOR QUESTIONS INCLUDED IN INDEX REFLECTING  
TV ANSWERS RELATING TO VIOLENCE AND LAW ENFORCEMENT

QUESTION ("TV ANSWER" UNDERLINED)	DATA SOURCE	"REAL WORLD"	"WORLD OF TELEVISION"
1. During any given week, what are your chances of being involved in some kind of violence? About one in ten? About 1 in 100?		.32 violent crimes per 100 people (1970 U.S. census)	64.4% of characters are involved in violence (Table 1)
2. What percent of all males who have jobs work in law enforcement and crime detection? One percent? <u>Five</u> percent?		1 % (1970 U.S. Census)	15% of all TV male characters
3. What percent of all crimes are violent crimes like murders, rape, robbery and aggravated assault? Fifteen percent? <u>Twenty-five</u> percent?		10 % (Statistical Abstract of the U.S., 1974)	77% of all TV major characters who commit crimes (as criminals) also commit violence
4. Does most fatal violence occur between <u>strangers</u> or between relatives or acquaintances?			(Cultural Indicators data, 1969-76)
		16 % of homicides occur between strangers, 64 % occur between family members or friends (National Commission on the Causes and Prevention of Violence, 1969)	58% of homicides committed by strangers (Cultural Indicators data, 1967-76)
